Tribhuvan University

## Lecture 02: Analysis of Algorithms

Data Structures

### What is a Problem

- A problem is
  - Something we want to solve,
  - Or a question we want to answer
- A computational problem is a general question to be answered
  - Generally has inputs, whose values are left unspecified, and the answers are the outputs

3

### Stating a problem

- Define the inputs, and what properties they must satisfy
- Define a relation between inputs and outputs, giving the properties a solution must satisfy

4

### Example

- Searching a sequence of integers
  - Input, sequence of integers,  $s$  and search value (an integer)
  - Output, index  $i$  such that  $s[i]=x$ , if one exists, otherwise  $i=-1$
- Searching an ordered sequence of integers
  - Input, sequence of integers,  $s$ , in ascending order and search value  $x$  (an integer), known to be in the sequence  $s$
  - Output, index  $I$  such that  $s[i]=x$

5

### Algorithms

- An algorithm is any well-defined computational procedure that takes some value, or set of values, as input and produces some value, or set of values, as outputs
- An algorithm is thus a sequence of computational steps that transform the input into the output

6

### Algorithm Properties

- **Inputs/Outputs:** There must be some inputs from the standard sets of inputs and an algorithm's execution must produce outputs
- **Definiteness:** Each must be clear and unambiguous
- **Finiteness:** Algorithms must terminate after finite time or steps
- **Effectiveness:** Every instruction must be basic enough to be carried out, in principle, by a person using only pencil and paper

7

### Correctness

- An algorithm is correct with respect to a problem if for every instances of the inputs
  - The algorithm halts
  - The outputs produced satisfy the input/output relation or produces correct output
- Correctness must be proven
  - An incorrect algorithm might not halt at all on some input instances, or it might halt with an answer other than the desired one

8

## Example

- ```
Factorial (int n)
if n = 2 then
    return 2
return factorial (n-1)*n
```
- We note that even though we may check the correctness of this algorithm for an infinity of values  $> 2$ , the algorithm is still incorrect as it does not halt on the case  $n = 1$

9

## Expressing Algorithms

- An algorithm can be specified
  - In English (eg enrollment guide)
  - By diagrams (eg instructions for assembling a kitset furniture)
  - In a computer programming language
  - With pseudo code
- The only requirement is that the specification must provide a precise description of the computational procedure to be followed

10

## Choice of Algorithms (1/2)

- On what basis, we should choose an algorithm
- Two contradictory goals
  - We would like an algorithm that is easy to understand, code and debug
  - We would like an algorithm that makes use efficient use of the computer resources, especially, one that runs as fast as possible

11

## Choice of Algorithms (2/2)

- Goal 1 is important when we are writing a program to be used once or a few times
  - Cost of the programmers' time will most likely exceed by far the cost of running the program
- Goal 2 is important when presented with a problem whose solution is to be used many times
  - Cost of running the program may far exceed the cost of writing it

12

## Analyzing Algorithms

- Analyzing an algorithm generally means predicting the resources that the algorithm requires
- Some of the resource that are of concern are: memory, communication bandwidth, or computer hardware
- Most important is computational time that we want to measure
- By analyzing several candidate algorithms for a problem, a most efficient one can be easily identified

13

## Performance Analysis

- We can analyze algorithms by determining the time and storage requirements of the algorithm
- The space complexity of a program is the amount of memory it needs to completion
- The time complexity of a program is the amount of computer time it needs to run to completion

14

## Space Complexity

- The space needed by a program is generally seen to be the sum of the following components
  - A fixed part that is independent of the characteristics (e.g., number, size) of the inputs and outputs
  - A variable part that consists of the space needed by component variables whose size is dependent on the particular problem instance being solved
- The space requirement  $S(P)$  of any program  $P$  is therefore be written as  $c + S_p(\text{instance characteristics})$  where  $c$  is a constant

15

## Example 1

- ```
float abc(float a, float b, float c)
{
    return a+b*b*c+(a+b-c)/(a+b)+4.0;
}
```
- Problem instance is characterized by the specific values of  $a$ ,  $b$ , and  $c$ .
- $S_p(\text{instance characteristics}) = 0$ 
  - No matter the values of  $a$ ,  $b$  and  $c$ , they always take same amount of memory

16

## Example 2

- ```
long int factorial(int n)
{
    int i;
    long int prod=1;
    for (i=2; i<=n; i++)
        prod *= i;
    return prod;
}
```
- $S_p(\text{instance characteristics}) = 0$

17

## Time Complexity

- The time complexity,  $T(P)$ , by a program  $P$  is the sum of the compile time and the run time.
- The compile time does not depend on the instance characteristics
- We concern ourselves with just the run time of a program

18

## Running Time

- The running time of an algorithm on a particular input is the number of primitive operations or steps executed
- Except for time of executing a function call most statements roughly require all the same amount of time
  - $Y=mx+c$
  - $C=5/9*(f-32)$
  - $Z=f(x)+g(y)$
- But we can be more exact if we need be

19

## Factors Effecting Running Time

- The running time of a program depends on factors such as:
  - The input to the program,
  - The quality of code generated by the compiler used to create the object program,
  - The nature and speed of the instructions on the machine used to execute the program, and
  - The time complexity of the algorithm underlying the program

20

## Program Step

- A program step is loosely defined as a syntactically or semantically meaningful segment of a program that has an execution time that is independent of the instance characteristics
- For example, the entire statement
  - `return a+b+b*c+(a+b-c)/(a+b)+4.0;`
  - Could be regarded as a step since its execution time is independent of instance characteristics
- Any statement that doesn't depend on instance characteristics can be regarded as a single step

21

## Input Size

- The time taken by an algorithm to solve a particular problem depends on the input
- The algorithm can take different amounts of time to solve the problem for two different input instances.
- In general, the time taken by an algorithm grows with the size of the input
- So we describe the running time of a program as a function of the size of its input
  - Time  $\propto f(n)$
  - Or equivalently,
  - Time =  $k * f(n)$  for some  $K$  that depends on the implementation

22

## Characteristics of Input Size

- How we characterize input size depends on the problem studied
  - Sorting: number of input items
  - Multiplication: total number of bits
  - Graph algorithms: number of nodes and edges

23

## Best, Worst and Average Case

- Best case complexity gives lower bound on the running time of the algorithm for any instance of inputs. This indicates that the algorithm can never have lower running time than best case for particular class of problems
- Worst case complexity gives upper bound on the running time of the algorithm for all instances of the inputs. This ensures that no input can overcome the running time limit posed by worst case complexity
- Average case complexity gives average number of steps required on any instance of the inputs random (equally likely) inputs, real-life inputs.

24

## Big-oh Notation

- $f(n) = O(g(n))$  (read as “ $f$  of  $n$  is big oh of  $g$  of  $n$ ”) iff (if and only if) there exists positive constants  $c$  and  $n_0$  such that  $f(n) \leq c \cdot g(n)$  for all  $n, n \geq n_0$
- Example
  - $3n+2 = O(n)$  as  $3n+2 \leq 4n$  for all  $n \geq 2$
  - $3n+3 = O(n)$  as  $3n+3 \leq 4n$  for all  $n \geq 3$
  - $100n+6 = O(n)$  as  $100n+6 \leq 101n$  for  $n \geq 10$

25

## Math you need to Review

- Summations
- Logarithms and Exponents

### properties of logarithms:

$$\begin{aligned}\log_b(xy) &= \log_b x + \log_b y \\ \log_b(x/y) &= \log_b x - \log_b y \\ \log_b x^a &= a \log_b x \\ \log_b a &= \log_x a / \log_x b\end{aligned}$$

### properties of exponentials:

$$\begin{aligned}a^{(b \cdot c)} &= (a^b)^c \\ a^{bc} &= (a^b)^c \\ a^b / a^c &= a^{(b-c)} \\ b &= a^{\log_a b} \\ b^c &= a^{c \log_a b}\end{aligned}$$

- Proof techniques
- Basic probability

26

## Big-oh Notation

27

## More Big-Oh Examples

### 7n-2

$f: \mathbb{R} \rightarrow \mathbb{R}, f(n) = 7n - 2$   
 $f(n) \leq 7n$  for all  $n \geq 0$   
 $f(n) \leq 7n$  for all  $n \geq 0$

### 6n^6 . 53n^5 . 8

$f: \mathbb{R} \rightarrow \mathbb{R}, f(n) = 6n^6 + 53n^5 + 8$   
 $f(n) \leq 6n^6 + 53n^5 + 8$  for all  $n \geq 0$   
 $f(n) \leq 6n^6 + 53n^5 + 8$  for all  $n \geq 0$

### 6n^j q . 8

$f: \mathbb{R} \rightarrow \mathbb{R}, f(n) = 6n^j q + 8$   
 $f(n) \leq 6n^j q + 8$  for all  $n \geq 0$   
 $f(n) \leq 6n^j q + 8$  for all  $n \geq 0$

28

The End
